Magnetic Resonance Imaging Improves 3-Month Outcome Prediction in Mild Traumatic Brain Injury

Esther L. Yuh, MD, PhD,[1,2] Pratik Mukherjee, MD, PhD,[1,2] Hester F. Lingsma, PhD,[3] John K. Yue, BS,[1,4] Adam R. Ferguson, PhD,[1,4] Wayne A. Gordon, PhD,[5] Alex B. Valadka, MD,[6] David M. Schnyer, PhD,[7] David O. Okonkwo, MD, PhD,[8] Andrew I. R. Maas, MD, PhD,[9] Geoffrey T. Manley, MD, PhD,[1,4] and the TRACK-TBI Investigators

Objective: To determine the clinical relevance, if any, of traumatic intracranial findings on early head computed tomography (CT) and brain magnetic resonance imaging (MRI) to 3-month outcome in mild traumatic brain injury (MTBI).
Methods: One hundred thirty-five MTBI patients evaluated for acute head injury in emergency departments of 3 LEVEL I trauma centers were enrolled prospectively. In addition to admission head CT, early brain MRI was performed 12 ± 3.9 days after injury. Univariate and multivariate logistic regression were used to assess for demographic, clinical, socioeconomic, CT, and MRI features that were predictive of Extended Glasgow Outcome Scale (GOS-E) at 3 months postinjury.
Results: Twenty-seven percent of MTBI patients with normal admission head CT had abnormal early brain MRI. CT evidence of subarachnoid hemorrhage was associated with a multivariate odds ratio of 3.5 ($p = 0.01$) for poorer 3-month outcome, after adjusting for demographic, clinical, and socioeconomic factors. One or more brain contusions on MRI, and ≥4 foci of hemorrhagic axonal injury on MRI, were each independently associated with poorer 3-month outcome, with multivariate odds ratios of 4.5 ($p = 0.01$) and 3.2 ($p = 0.03$), respectively, after adjusting for head CT findings and demographic, clinical, and socioeconomic factors.
Interpretation: In this prospective multicenter observational study, the clinical relevance of abnormal findings on early brain imaging after MTBI is demonstrated. The addition of early CT and MRI markers to a prognostic model based on previously known demographic, clinical, and socioeconomic predictors resulted in a >2-fold increase in the explained variance in 3-month GOS-E.

ANN NEUROL 2013;73:224–235

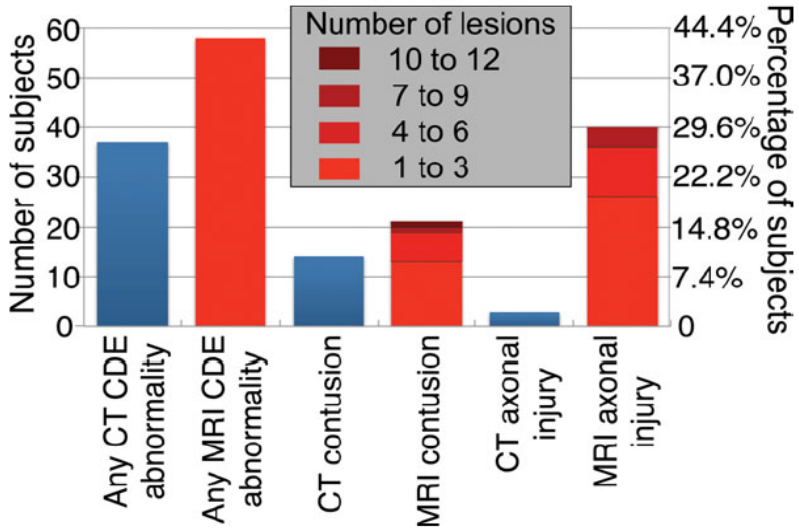

FIGURE 1: Incidence of computed tomography (CT) versus magnetic resonance imaging (MRI) traumatic brain injury common data element (CDE) abnormalities in 135 study participants. For MRI evidence of contusion and MRI evidence of hemorrhagic axonal injury, progressively darker shades of red indicate larger numbers of lesions (*gray legend*). Study participants with CT evidence of brain contusion had, in most cases, evidence of 1 or 2 hemorrhagic contusions, with no CT demonstrating >3 convincing brain contusions. CT showed evidence of hemorrhagic axonal injury in 3 of 135 study participants, all with 1 to 3 foci of injury. Objective Biomarkers of Injury & Recovery

Clinical Utility of Biomarkers

Measurement of the Glial Fibrillary Acidic Protein and Its Breakdown Products GFAP-BDP Biomarker for the Detection of Traumatic Brain Injury Compared to Computed Tomography and Magnetic Resonance Imaging

Abstract

Glial fibrillary acidic protein and its breakdown products (GFAP-BDP) are brain-specific proteins released into serum as part of the pathophysiological response after traumatic brain injury (TBI). We performed a multi-center trial to validate and characterize the use of GFAP-BDP levels in the diagnosis of intracranial injury in a broad population of patients with a positive clinical screen for head injury. This multi-center, prospective, cohort study included patients 16–93 years of age presenting to three level 1 trauma centers with suspected TBI (loss of consciousness, post-trauma amnesia, and so on). Serum GFAP-BDP levels were drawn within 24 h and analyzed, in a blinded fashion, using sandwich enzyme-linked immunosorbent assay. The ability of GFAP-BDP to predict intracranial injury on admission computed tomography (CT) as well as delayed magnetic resonance imaging was analyzed by multiple regression and assessed by the area under the receiver operating characteristic curve (AUC). Utility of GFAP-BDP to predict injury and reduce unnecessary CT scans was assessed utilizing decision curve analysis. A total of 215 patients were included, of which 83% suffered mild TBI, 4% moderate, and 12% severe; mean age was 42.1 ± 18 years. Evidence of intracranial injury was present in 51% of the sample (median Rotterdam Score, 2; interquartile range, 2). GFAP-BDP demonstrated very good predictive ability (AUC = 0.87) and demonstrated significant discrimination of injury severity (odds ratio, 1.45; 95% confidence interval, 1.29–1.64). Use of GFAP-BDP yielded a net benefit above clinical screening alone and a net reduction in unnecessary scans by 12–30%. Used in conjunction with other clinical information, rapid measurement of GFAP-BDP is useful in establishing or excluding the diagnosis of radiographically apparent intracranial injury throughout the spectrum of TBI. As an adjunct to current screening practices, GFAP-BDP may help avoid unnecessary CT scans without sacrificing sensitivity (Registry: ClinicalTrials.gov Identifier: NCT01565551).

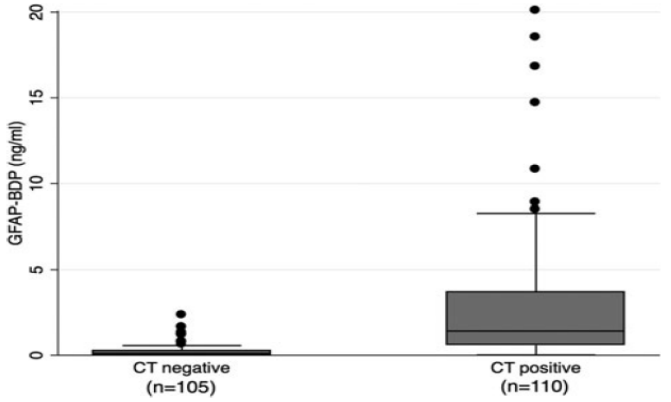

FIG. 1. Box plots showing median levels of GFAP-BDP measured on admission in two groups of patients. Boxes show interquartile ranges, and I bars represent highest and lowest values. CT, computed tomography;GFAP-BDP, glial fibrillary acidic protein and its breakdown products.

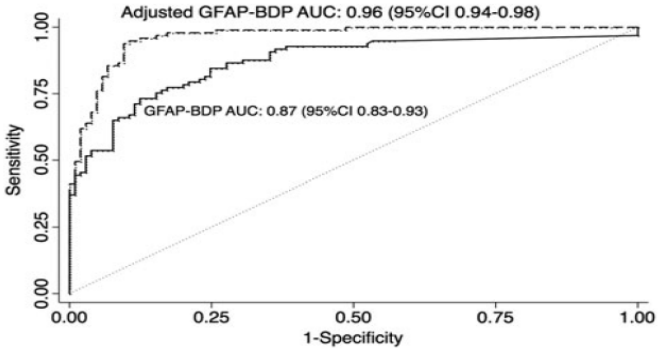

FIG. 3. Receiver-operating-characteristic curves for various cut-off levels of GFAP-BDP in differentiating presence or absence of intracranial injury on CT. Curves for GFAP-BDP alone and after adjustment for known predictors of injury and severity (age, GCS, pupillary reactivity, and ISS). AUC, area under the receiver operating characteristic curve; CI, confidence intreval; CT, computed tomography; GCS, Glasgow Coma Scale; GFAP-BDP, glial fibrillary acidic protein and its breakdown products; ISS, Injury Severity Scale.

TBI Outcome Measurement

Glasgow Outcome Scale – Extended (GOSE)

1	**Dead**	
2	**Vegetative State (VS)**	Condition of unawareness with only reflex responses but with periods of spontaneous eye opening
3	**Severe Disability – Lower (SD–)**	Dependence on daily support for mental or physical disability or both. If the patient can be left alone for more than 8 hours at home, it is upper level of SD; if not, then it is low level of SD
4	**Severe Disability – Upper (SD+)**	
5	**Moderate Disability – Lower (MD–)**	Patients have some disability such as aphasia, hemiparesis or epilepsy and/or deficits of memory or personality but are able to look after themselves. They are independent at home but dependent outside. If they are able to return to work event with special arrangement it is upper level of MD; if not then it is low level of MD.
6	**Moderate Disability – Upper (MD+)**	
7	**Good Recovery – Lower (GR–)**	Resumption of normal life with the capacity to work even if pre-injury status has not been achieved. Some patients have minor neurological or psychological deficits. If these deficits are not disabling then it is upper level of GR; if disabling, then it is lower level of GR.
8	**Good Recovery – Upper (GR+)**

Validating Multi-Dimensional Outcome Assessment Using the Traumatic Brain Injury Common Data Elements: An Analysis of the TRACK-TBI Pilot Study Sample

Lindsay D. Nelson,[1] Jana Ranson,[2] Adam R. Ferguson,[3] Joseph Giacino,[4] David O. Okonkwo,[5] Alex B. Valadka,[6] Geoffrey T. Manley,[7] Michael A. McCrea,[1] and the TRACK-TBI Investigators

Abstract

The Glasgow Outcome Scale-Extended (GOSE) is often the primary outcome measure in clinical trials for traumatic brain injury (TBI). Although the GOSE's capture of global functional outcome has several strengths, concerns have been raised about its limited ability to identify mild disability and failure to capture the full scope of problems patients exhibit after TBI. This analysis examined the convergence of disability ratings across a multi-dimensional set of outcome domains in the Transforming Research and Clinical Knowledge in Traumatic Brain Injury (TRACK-TBI) Pilot Study. The study collected measures recommended by the TBI Common Data Elements (CDE) Workgroup. Patients presenting to three emergency departments with a TBI of any severity enrolled in TRACK-TBI prospectively after injury; outcome measures were collected at 3 and 6 months post-injury. Analyses examined frequency of impairment and overlap between impairment status across the CDE outcome domains of Global Level of Functioning (GOSE), Neuropsychological (cognitive) Impairment, Psychological Status, TBI Symptoms, and Quality of Life. GOSE score correlated in the expected direction with other outcomes (mean [*M*] Spearman's rho = 0.21 and 0.49 with neurocognitive and self-report outcomes, respectively). The subsample in the Upper Good Recovery (GOSE 8) category appeared quite healthy across most other outcomes, although 19.0% had impaired executive functioning (Trail Making Test Part B). A significant minority of participants in the Lower Good Recovery subgroup (GOSE 7) met criteria for impairment across numerous other outcome measures. The findings highlight the multi-dimensional nature of TBI recovery and the limitations of applying only a single outcome measure.
